

Alerts

This project is using [react-toastify](#) to handle alerts. If you want more in-depth info about them please refer to the [documentation](#).

Usage

Here is an exemple of how you can create an alert.

React

```
import React from "react";
import { toast } from "react-toastify";

export default function myComponent() {
  const iWasPressed = () => {
    // This will show an error alert.
    toast.error("Não foi possível acessar o backend");
  };

  return(
    <button onClick={iWasPressed}>
      Press me :D
    </button>
  );
}
```
