Alerts

This project is using react-toastify to handle alerts. If you want more in-depth info about them please refer to the documentation.

Usage

Here is an exemple of how you can create an alert.

```
import React from "react";
import { toast } from "react-toastify";

export default function myComponent() {
  const iWasPressed = () => {
    // This will show an error alert.
    toast.error("Não foi possível acessar o backend");
  };

return(
    <button onClick={iWasPressed}>
        Press me :D
        </button>
  );
}
```
